1 Equalizers, Kernels, and Ideals

1.1 Equalizers and coequalizers

Definition 1.1. Let $f, g : A \rightarrow B$ be morphisms in \mathcal{C} . The **equalizer** is the limit of the diagram

$$A \begin{array}{c} \xrightarrow{f} \\ \xrightarrow{g} \end{array} B$$

It satisfies the following diagram:

$$\begin{array}{ccc} \text{eq}(f, g) & \xrightarrow{\iota} & A \begin{array}{c} \xrightarrow{f} \\ \xrightarrow{g} \end{array} B \\ \uparrow \text{dashed} & \nearrow q & \\ Y & & \end{array}$$

A **coequalizer** is the colimit of the diagram

$$A \begin{array}{c} \xrightarrow{f} \\ \xrightarrow{g} \end{array} B$$

It satisfies the following diagram:

$$\begin{array}{ccc} A \begin{array}{c} \xrightarrow{f} \\ \xrightarrow{g} \end{array} B & \xrightarrow{\pi} & \text{coeq}(f, g) \\ & \searrow q & \downarrow \text{dashed} \\ & & Y \end{array}$$

Lemma 1.1. $\iota : \text{eq}(f, g) \rightarrow A$ is a monomorphism, and $\pi : B \rightarrow \text{coeq}(f, g)$ is an epimorphism.

Proof. Let $\alpha, \beta : C \rightarrow \text{eq}(f, g)$ be such that $\iota \circ \alpha = \iota \circ \beta$. Then there is a unique morphism $\phi : C \rightarrow \text{eq}(f, g)$ making the following diagram commute:

$$\begin{array}{ccc} \text{eq}(f, g) & \xrightarrow{\iota} & A \xrightleftharpoons[g]{f} B \\ \uparrow \phi & \nearrow \iota \circ \alpha & \nearrow \iota \circ \beta \\ C & & \end{array}$$

But α and β satisfy the property of ϕ , so $\alpha = \phi = \beta$. The property for coequalizers follows from reversing the arrows. \square

Theorem 1.1. *Every category with products and equalizers is complete.*

Proof. Let $F : I \rightarrow \mathcal{C}$ be a functor. Then

$$\prod_{i \in I} F(i) \xrightleftharpoons[g]{f} \prod_{\phi: i \rightarrow \phi(i)} F(\phi(i))$$

where f is

$$\prod_{k \in I} F(k) \xrightarrow{\pi_i} F(i) \xrightarrow{F(\phi)} F(\phi(i))$$

and g is

$$\prod_{k \in I} F(k) \xrightarrow{\pi_{\pi(i)}} F(\phi(i))$$

We claim that $\text{eq}(f, g) \rightarrow \prod_{i \in I} F(i) \rightarrow F(i)$ is the limit. The

$$\begin{array}{ccc} \text{eq}(f, g) & \longrightarrow & F(i) \\ & \searrow & \downarrow F(\phi) \\ & & F(\phi(i)) \end{array}$$

commute for all ϕ . So the equalizer has the property of the limit. To show the universal property, suppose we have the following diagram for some X .

$$\begin{array}{ccc} X & \xrightarrow{\psi_i} & F(i) \\ & \searrow \psi_{\phi(i)} & \downarrow F(\phi) \\ & & F(\phi(i)) \end{array}$$

This is the same as

$$\begin{array}{ccccc} X & \longrightarrow & \prod_{i \in I} F(i) & \xrightleftharpoons[g]{f} & \prod_{\phi: i \rightarrow \phi(i)} F(\phi(i)) \\ \downarrow & \nearrow & & & \\ \text{eq}(f, g) & & & & \end{array}$$

by the universal property of the equalizer. So $\text{eq}(f, g)$ satisfies the universal property of $\lim F$. \square

Example 1.1. In Set , Gp , Ring , Rmod , and Top , the equalizer of $f, g : A \rightarrow B$ $\text{eq}(f, g) = \{x \in A : f(x) = g(x)\}$. These are all complete categories. They are also complete, as they have coproducts and coequalizers.

1.2 Kernels and ideals

Definition 1.2. A **zero object** is an object which is both initial and terminal.

Let \mathcal{C} have a zero object 0 . There exists a unique morphism $0 : A \rightarrow B$ which is the composition of the unique morphism from $A \rightarrow 0$ and $0 \rightarrow B$.

Definition 1.3. For $f : A \rightarrow B$, the **kernel** $\ker(f) = \text{eq}(f, 0)$ and $\text{coker}(f) = \text{coeq}(f, 0)$, where 0 is the unique zero morphism.

Example 1.2. In Gp , $\ker(f : G \rightarrow G') = \{g \in G : f(g) = e\}$. This is the same in Rmod .

Example 1.3. In Ring , we can make sense of this if we work in a larger category, Rng , of pseudorings (rings without identity). If $f : R \rightarrow S$, then $\ker(f) = \{x \in R : f(x) = 0\}$. In fact, $\ker f$ is a two-sided ideal.

In all of these cases, $\ker f = 0$ iff f is a monomorphism iff f is 1 to 1. To show that $\ker(f) = 0$ implies that f is a monomorphism, we have (in Gp)

$$f(g) = f(h) \implies f(gh^{-1}) = e \implies gh^{-1} = e \implies g = h,$$

but this requires internal knowledge of the structure of the category.

Proposition 1.1. 1. If $f : G \rightarrow G'$ is a homomorphism, $\ker(f) \trianglelefteq G$.

2. If $N \trianglelefteq G$, then $N = \ker(\pi)$, where $f : G \rightarrow G/N$ sends $g \mapsto gN$.

Proof. To prove the first part, note that $f(gng^{-1}) = f(g)f(n)f(g)^{-1} = e$, so $gng^{-1} \in \ker(f)$. The second follows from the definitions. \square

Theorem 1.2. Let $f : G \rightarrow G'$ be a homomorphism. Then $\bar{f} : G/\ker(f) \rightarrow \text{im}(f)$ given by $\bar{f}(g\ker(f)) = f(g)$ is an isomorphism.

Definition 1.4. A **left ideal** I of a ring R is a subgroup such that $ri \in I$ for all $r \in R$ and $i \in I$. A **right ideal** I of a ring R is a subgroup such that $is \in I$ for all $s \in R$ and $i \in I$. A **(two-sided) ideal** I is a right and left ideal.

If we have a left ideal I , left multiplication $R \times I \rightarrow I$ makes I a left R -module. So a left ideal of R is exactly a left R -submodule of R .

Definition 1.5. An (R, S) -**bimodule** M is a left R -module that is also a right S -module such that $(rm)s = r(ms)$ for all $r \in R$, $s \in S$, and $m \in M$.

A (two-sided) ideal is an (R, R) -subbimodule of R .

If $I \subseteq R$ is a two-sided ideal, then $R/I = \{a + I : a \in R\}$. We have addition $(a + I) + (b + I) = (a + b) + I$ and multiplication $(a + I)(b + I) = ab + I$. Why is multiplication well-defined? For $a, b \in R$ and $i, j \in I$,

$$(a + i)(b + j) = ab + \underbrace{aj}_{\in I} + \underbrace{ib}_{\in I} + \underbrace{ij}_{\in I} \in ab + I.$$

Definition 1.6. R/I is called a **quotient ring**.

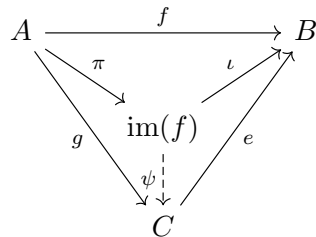

Observe that $\ker(f)$ with $f : R \rightarrow S$ is an ideal. If $a \in \ker(f)$, $r, s \in R$, then $f(ras) = f(r)f(a)f(s) = 0$. So we have the $\pi : R \rightarrow R/I$ with $\pi(r) = r + I$ and $\ker(\pi) = I$. So $R/\ker(f) \cong \text{im}(f)$.

This also works with left, right, and bimodules. In fact, it works even better! All left R -modules are kernels, so you don't need any conditions like normality.

What about cokernels? In \mathbf{Gp} , we have a problem: if $f : G \rightarrow G'$, $\text{im}(f)$ may not be normal in G' . We take $\text{coker}(f) = G/\overline{\text{im}(f)}$, where $\overline{\text{im}(f)}$ denotes the **normal closure** of $\text{im}(f)$, the smallest normal subgroup containing $\text{im}(f)$.

We have been using the term image in the sense of groups. Here is a categorical point of view.

Definition 1.7. The **image** $\text{im}(f)$ of $f : A \rightarrow B$ is an object and a monomorphism $\iota : \text{im}(f) \rightarrow B$ such that there exists $\pi : A \rightarrow \text{im}(f)$ with $\pi \circ \iota = f$ and such that if $e : C \rightarrow B$ is a monomorphism and $g : A \rightarrow C$ is such that $e \circ g = f$, then there exists a unique morphism $\psi : \text{im}(f) \rightarrow C$ such that $g \circ \psi = e$.

Note that $e \circ \psi \circ \pi = e \circ g \implies \psi \circ \pi = g$, since e is a monomorphism.
